Homework 5 - AGST 5014

Igor Kuivjogi Fernandes and Ashmita Upadhyay

2023-03-09

1. The following data set has 2 mistakes. Find the issue and analyze the experiment. Include all the necessary analysis and interpretation

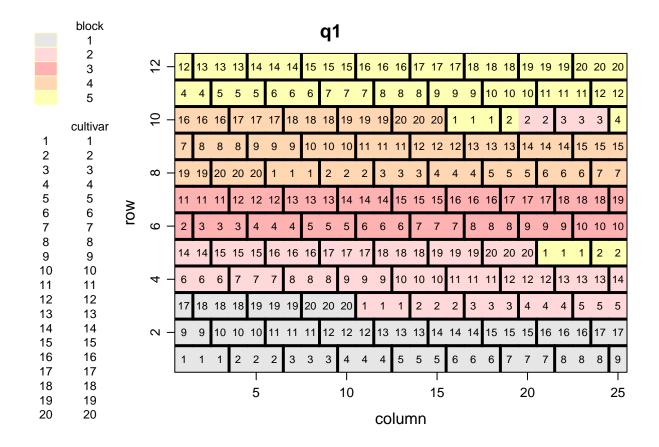

```
q1 <- read.csv("HW5_Q1_fixed.csv")
q1$fertilizer_application <- NULL
q1$rep <- NULL
factor_cols <- c("row", "column", "cultivar", "fer", "block")</pre>
q1[factor_cols] <- lapply(q1[factor_cols], as.factor)</pre>
str(q1)
## 'data.frame':
                    300 obs. of 7 variables:
              : int 1 2 3 4 5 6 7 8 9 10 ...
              : Factor w/ 12 levels "1","2","3","4",...: 1 1 1 1 1 1 1 1 1 1 1 ...
   $ column : Factor w/ 25 levels "1", "2", "3", "4", ...: 1 2 3 4 5 6 7 8 9 10 ...
  $ cultivar: Factor w/ 20 levels "1","2","3","4",..: 1 1 1 2 2 2 3 3 3 4 ...
              : num 82.4 67.2 255.1 186.6 139.1 ...
   $ y
              : Factor w/ 5 levels "1", "2", "3", "4", ...: 1 1 1 1 1 1 1 1 1 1 ...
    $ block
    $ fer
              : Factor w/ 3 levels "April", "June", ...: 1 2 3 1 2 3 1 2 3 1 ...
We have 12 rows and 25 columns.
```

```
q1[rownames(q1) %in% c(60, 160), ]
##
       plot row column cultivar
                                         y block
                                                    fer
## 60
        160
              3
                    10
                              20 104.71737
                                                1
                                                    May
## 160
         60
              7
                    10
                              14 50.57193
                                                3 April
```

The plot 160 should be labelled as 60, and the plot 60 should be labelled as 160.

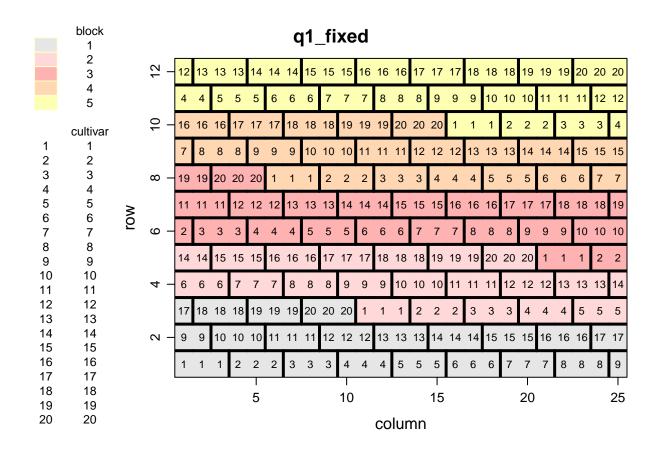

```
desplot::desplot(
  q1,
  block ~ column * row,
  cex = 0.7,
  text = cultivar,
  out1 = cultivar,
  ticks = T
)
```

The row 5 with columns 21 to 25 should be labelled as block 3 rather than block 5. The row 8 with columns 1 to 5 should be labelled as block 3 rather than block 4. The row 10 with columns 20 to 24 should be labelled as block 5 rather than block 2. Fixing this, now each cultivar appears only once within each block.

Fixing errors:

```
q1_fixed <- q1
# fixing plots
q1_fixed[rownames(q1_fixed) == 60, 'plot'] <- 60
q1_fixed[rownames(q1_fixed) == 160, 'plot'] <- 160
# fixing blocks
q1_fixed[(q1_fixed$row == 5) & (q1_fixed$column %in% 21:25), 'block'] <- 3
q1_fixed[(q1_fixed$row == 8) & (q1_fixed$column %in% 1:5), 'block'] <- 3
q1_fixed[(q1_fixed$row == 10) & (q1_fixed$column %in% 20:24), 'block'] <- 5
desplot::desplot(
  q1_fixed,
  block ~ column * row,
  cex = 0.7,
 text = cultivar,
  out1 = cultivar,
  ticks = T
)
```

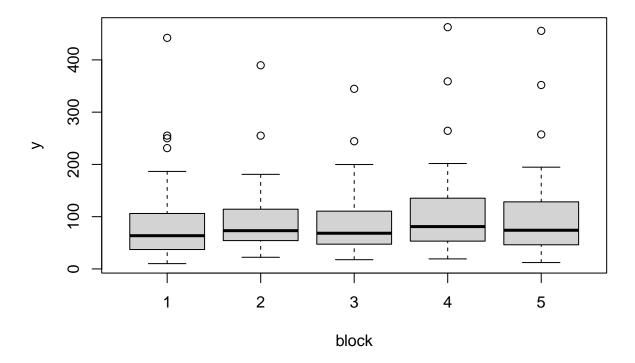

```
table(q1_fixed$block, q1_fixed$cultivar, dnn = c('block', 'cultivar'))
```

```

##
```

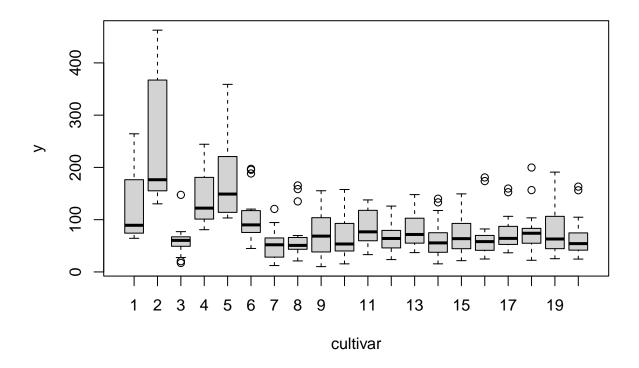

Now we have the 3 eu's for each block/cultivar combination.

Let's do the analysis now.

```
boxplot(y ~ block, data = q1_fixed)
```

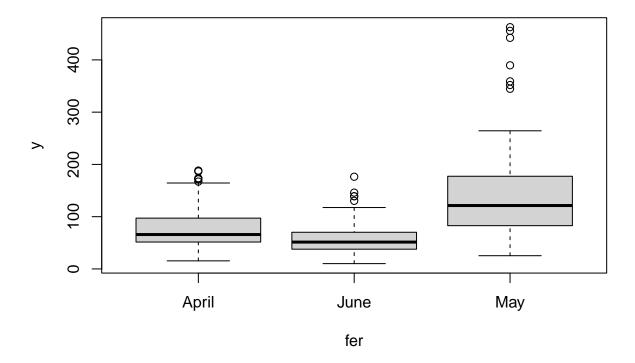

The yield has very similar distribution between blocks.

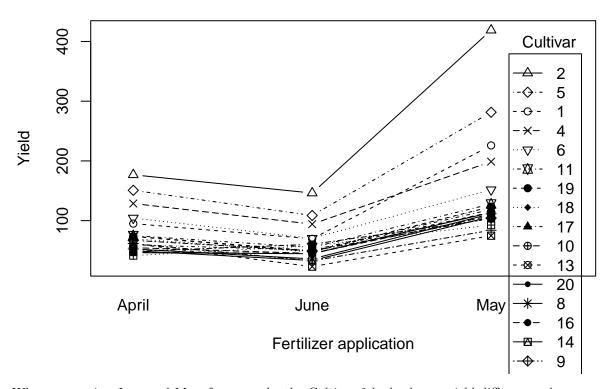

Some cultivar (e.g. 1, 2, and 5) had a larger yield than others.

boxplot(y ~ fer, data = q1_fixed)

The yield in May was larger than the other months.

Interaction Plot of Fertilizer application and Cultivar

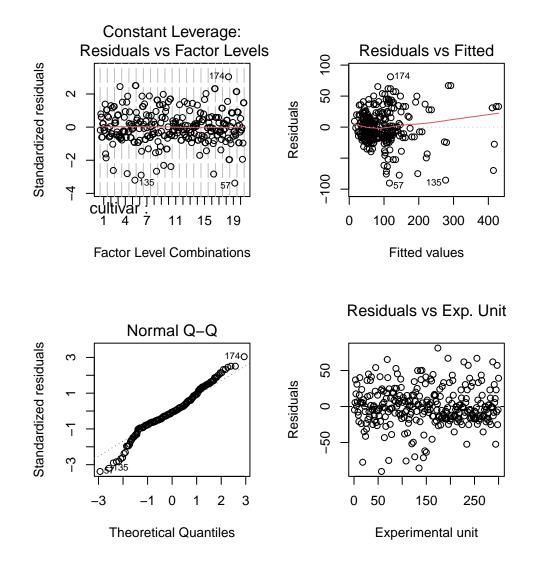

When comparing June and May, for example, the Cultivar 2 had a larger yield difference when comparing to other cultivars, so seems there's an interaction between cultivar and fertilizer application.

Let's fit an ANOVA now:

```
fit <- aov(y ~ cultivar * fer + block, data = q1_fixed)</pre>
summary(fit)
##
                 Df Sum Sq Mean Sq F value

```

Using an significance level of $\alpha = 0.05$, the cultivar, fertilizer application, and the interaction are significant, because all the p-values are lower than α .

The homogeneous of variance between different cultivar levels seems to be present.

We have a horizontal pattern across the experimental units.

130.1677

1

##

The normality of residuals was not met, maybe because the yield distribution is very skewed but we don't know whether the big values (from May fertilizer application) of yield are outliers or not. Maybe we could try to transform the data or use a GLM, for example, but we will stick with this model.

We can do a Tukey's test of multiple comparison to check the best cultivar:

```
ExpDes::tukey(q1_fixed$y, q1_fixed$cultivar, DFerror = 236, SSerror = 213971)

##
## Tukey's test

The cultivar 2 has a higher mean yield than all the others, using a significance level of $\alpha = 0.05$.

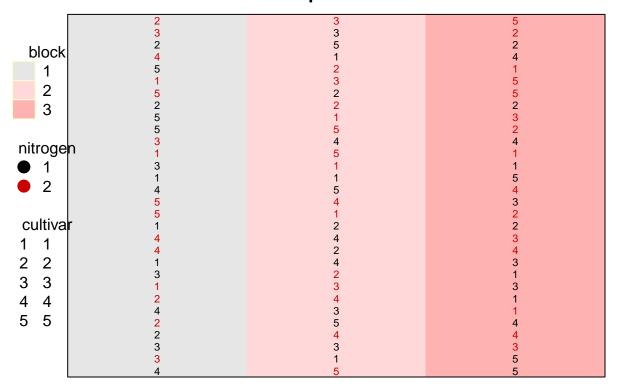

- 2. Design an experiment to answer the following questions (Attach the CSV file and include below a figure with the layout of your experiment):
 - a) Does increasing the dose of nitrogen affect yield? Does it depend on the frequency of irrigation? or on the cultivar? In the allocated field, I have some areas that are more fertile than others. I have resources for a total of 90 EU.
 - Let's say we have two doses of nitrogen 1 and 2, frequency of irrigation 0 and 10, 5 different cultivars, and a block to account for 3 subgroups (different fertile area gradients).

```
set.seed(2023)
grid <- expand.grid(nitrogen = 1:2, freq_irrigation = c(0, 10, 20), cultivar = 1:5)
# randomize block 1
b1 <- grid
b1$block <- 1
b1 <- b1[sample(1:nrow(b1)), ]
b1$row <- 1:nrow(b1)
b1$col <- 1
b1$yield <- rnorm(nrow(b1), 10, 1) # low yield
# randomize block 2
b2 <- grid
b2$block <- 2
b2 <- b2[sample(1:nrow(b2)), ]
b2$row <- 1:nrow(b2)
b2$co1 <- 2
b2$yield <- rnorm(nrow(b2), 14, 1.2) # medium yield
# randomize block 3
b3 <- grid
b3$block <- 3
b3 <- b3[sample(1:nrow(b3)), ]
b3$row <- 1:nrow(b3)
b3$col <- 3
```

The layout:

```
desplot::desplot(
  exp1,
  block ~ col * row,
  text = cultivar,
  col = nitrogen,
  cex = 0.7
)
```

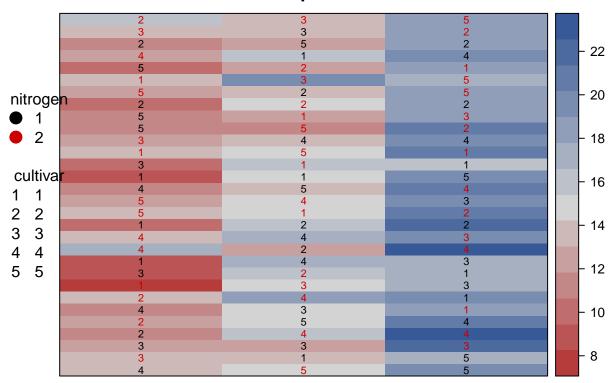

exp1

Each block represent a different fertile area that affects the yield. This effect could be seem using the color as the response:

```
desplot::desplot(
  exp1,
  yield ~ col * row,
  text = cultivar,
  col = nitrogen,
  cex = 0.7
)
```

```
fit <- aov(yield ~ nitrogen * freq_irrigation * cultivar + block, data = exp1)
summary(fit)</pre>
```

```

```

Using a significance level of $\alpha=0.05$, the dose of nitrogen affects the yield, the frequency of irrigation also affects the yield, so as the cultivar. The interaction 'freq_irrigation:cultivar' is also significant, but the others interactions are not.

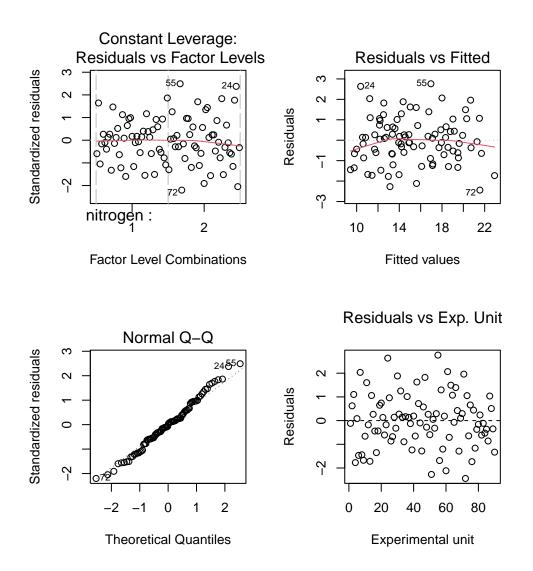

The block effect was important to control the errors because it has a large mean sum of squares compared to the residuals.

In fact, if we do not account for a blocking effect, all the terms would not be significant:

```
summary(aov(yield ~ nitrogen * freq_irrigation * cultivar, data = exp1))
```

```

```

Let's look to the residuals:

We have homogeneous of variance between nitrogen doses, the residuals look normal, and there's a horizontal pattern across the experimental units.

b) Is there a variation in bacteria/fungus growth with different agar types (semi-solid, gel-like state)? I have 30 plates (experimental unit) available.

If we have 30 experimental units and two levels, so the rep is 2.

```
set.seed(2023)
f <- c(rep('semi-solid', 15), rep('gel-like', 15))
sampled <- sample(f)
eu <- 1:length(sampled)
exp2 <- data.frame(eu = eu, agar = sampled, growth = rnorm(30, 5, 1))
exp2$agar <- factor(exp2$agar, levels = c('semi-solid', 'gel-like')) # change level order
# gel-like agar favors yield
exp2[exp2$agar == 'gel-like', 'growth'] <- (</pre>
```

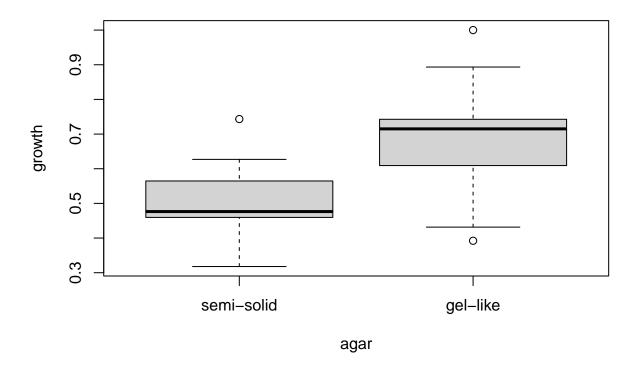

```
exp2[exp2$agar == 'gel-like', 'growth'] + rnorm(15, 1, 1)
)

# normalize growth to the interval [0, 1]
exp2$growth <- exp2$growth / max(exp2$growth)
str(exp2)

## 'data.frame': 30 obs. of 3 variables:
## $ eu : int 1 2 3 4 5 6 7 8 9 10 ...
## $ agar : Factor w/ 2 levels "semi-solid", "gel-like": 2 2 1 1 1 2 1 1 2 1 ...
## $ growth: num 0.729 0.739 0.463 0.474 0.627 ...</pre>
```

Let's do the analysis.

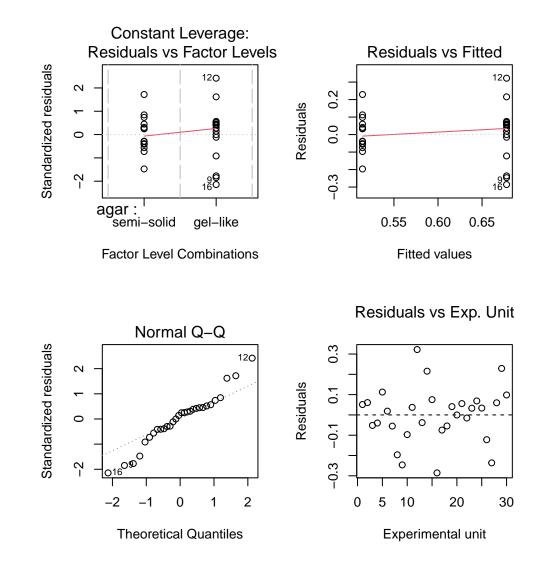

```
boxplot(growth ~ agar, data = exp2)
```

The bacteria growth for gel-like agar is larger than for semi-solid. Fitting an one-way ANOVA:

```
## Residuals 28 0.5327 0.01902
## ---
## Signif. codes: 0 '*** 0.001 '** 0.05 '.' 0.1 ' ' 1
```

The agar type affects the bacteria growth, using an significance level of $\alpha = 0.05$, because the p-value $< \alpha$. Residuals:

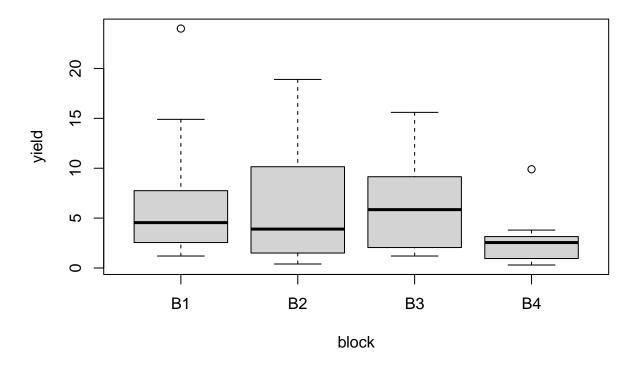

The variances are homogeneous between different agar types, the residuals seems to be normally distributed (although there are some deviance in the tails), and there is a horizontal pattern across the experimental units.

```
shapiro.test(residuals(fit))
##
##
    Shapiro-Wilk normality test
##
## data: residuals(fit)
## W = 0.96158, p-value = 0.3397
The Shapiro-Wilk test confirms the residuals are normally distributed, because the p-value > \alpha, using a
significance level of \alpha = 0.05, which means we do not reject the mull hypothesis that the residuals are
normally distributed.
3. The data set mcconway.turnip from the package agridat presents us with an RCBD experiment
of turnips with 16 treatments allocated at random to each of four blocks The 16 treatments
were combinations of two varieties, two planting dates, and four densities.
  a) Run anova as usual. Are the requirements met?
q3 <- agridat::mcconway.turnip
q3[c('gen', 'date', 'density')] <- lapply(q3[c('gen', 'date', 'density')], as.factor)
str(q3)
                     64 obs. of 5 variables:
## 'data.frame':
    $ gen
             : Factor w/ 2 levels "Barkant", "Marco": 1 1 1 1 1 1 1 1 1 1 ...
           : Factor w/ 2 levels "21Aug1990","28Aug1990": 1 1 1 1 1 1 1 1 1 1 ...
## $ density: Factor w/ 4 levels "1","2","4","8": 1 1 1 1 2 2 2 2 3 3 ...
## $ block : Factor w/ 4 levels "B1", "B2", "B3", ...: 1 2 3 4 1 2 3 4 1 2 ...
## $ yield : num 2.7 1.4 1.2 3.8 7.3 3.8 3 1.2 6.5 4.6 ...
# checking frequency tables
with(q3, table(gen, date))
##
            date
## gen
             21Aug1990 28Aug1990
##
     Barkant
                     16
                               16
##
     Marco
                     16
                               16
with(q3, table(gen, density))
##
            density
## gen
             1 2 4 8
     Barkant 8 8 8 8
##
##
     Marco
             8 8 8 8
with(q3, table(date, density))
##
              density
## date
               1 2 4 8
     21Aug1990 8 8 8 8
##
     28Aug1990 8 8 8 8
```

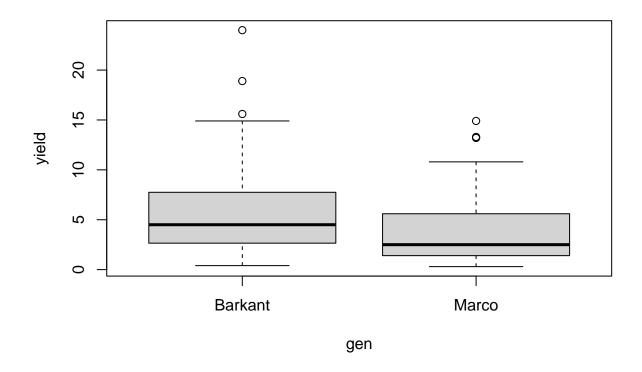

The data is balanced.

boxplot(yield ~ block, data = q3)

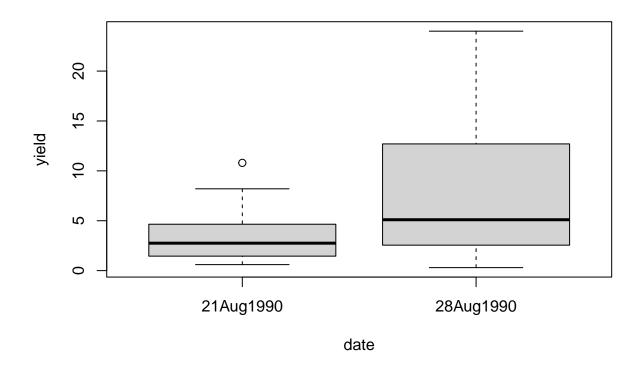

For the block B4, we have very low yield compared to the other ones.

boxplot(yield ~ gen, data = q3)

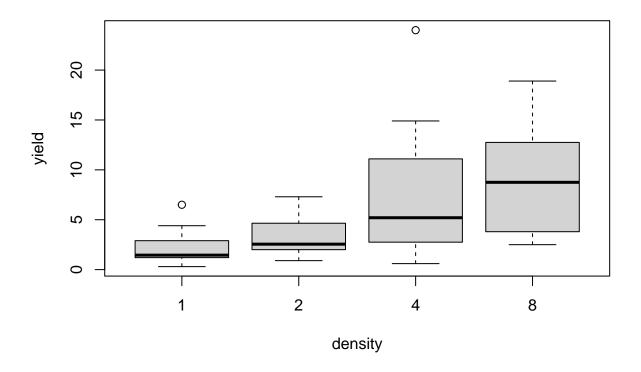

The yield is slightly higher for Barkant.

boxplot(yield ~ date, data = q3)

The yield was way larger for the 28 Aug 1990.

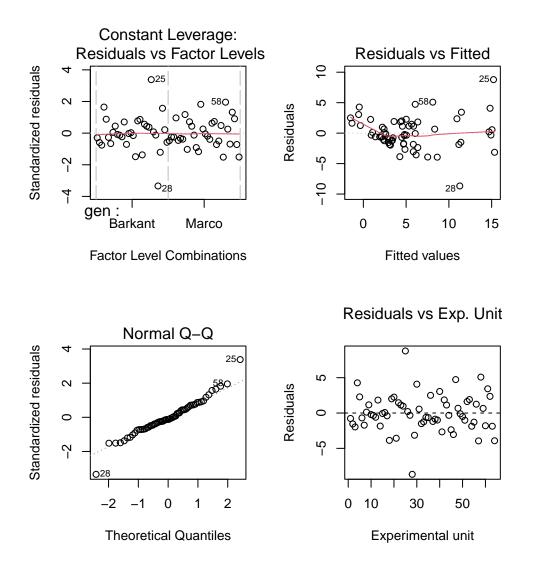

boxplot(yield ~ density, data = q3)

Seems the yield increases as the density increases.

Let's fit an ANOVA:

```
fit <- aov(yield ~ gen * date * density + block, data = q3)
summary(fit)
##
                    Df Sum Sq Mean Sq F value
                                                 Pr(>F)
                         84.0

```
##
## Shapiro-Wilk normality test
##
## data: residuals(fit)
## W = 0.96283, p-value = 0.05116
```

Some residuals points has deviations from the QQ line, but from the Shapiro-Wilk test we do not reject the null hypothesis that the residuals are normally distributed.

The residuals seems have homogeneous variance between the varieties, and the residuals show horizontal pattern across the experimental units, using a significance level of $\alpha = 0.05$.

One problem is that seems the residual's variance increases as the fitted values increase, so the ANOVA assumptions were not met, although this problem might be solved using a target transformation, for example.

- b) Run a mixed model considering block as a random term.
- c) If there is any issue with the data that result in not meeting the ANOVA assumptions, use a mixed model to solve it.
